

**Quantachrome Instruments Workshop on Methods of Characterization and Evaluation  
of Adsorbents for Industrial Applications**

**Thursday, November 2, 10:30–11:00 AM  
Minneapolis Convention Center, Room 101J**

Matthias Thommes

**Progress and Challenges in the Structural Characterization of Nanoporous Materials by Physical Adsorption**

Assessing adsorption properties of nanoporous materials (e.g. for gas storage applications) and their structural characterization is crucial for advancing the application of nanoporous materials such as mesoporous zeolites in catalysis, separations, and other industrial processes. Gas adsorption is well suited for this task because it assesses a wide range of pore sizes, spanning the entire micro- and mesopore range. Within the last two decades major progress has been achieved in the understanding of the adsorption and phase behaviour of fluids in ordered nanoporous materials and in the development of advanced approaches based on statistical mechanics such as molecular simulation and density functional theory of inhomogeneous fluids (see reviews [1,2] and references therein). This progress, coupled with the availability of high resolution experimental procedures for the adsorption of various subcritical fluids, has led to major advances in the structural characterization by physical adsorption. These advances and corresponding recommendations for physisorption characterization are also summarized in a new IUPAC technical report which has been very recently published (in 2015, ref. [3]).

Within this context we will discuss in important fundamental aspects of the underlying adsorption mechanisms of fluids in nanoporous materials (e.g., micro-mesoporous materials with hierarchical pore structure [4]) and their significance for physical adsorption characterization
